0.1 mol. solution For the hydrolysis constant,  $K_h = 0.55 \cdot 10^{-4}$  was calculated  
From this value  $\text{HAuCl}_4$  should be hydrolyzed 0.74% in 1 mol. and 45.0% in  
0.01 mol. solution The anal., electrometric and spectrophotometric data are  
presented in 55 tables.

AB A routine procedure for EM radioautography in combination with phenidon  
developer and the domestic emulsion, Sakura NR-H2, was developed. Good  
stable radioautograms were not obtained by simply developing the emulsion  
coated grids with phenidon developer at any temperature, but the  
development of these grids at  $18^\circ \text{C}$  for 1 min after 30-45 s Au  
latensification in freshly prepared **gold thiocyanate**  
gives satisfactory results. Some EM radioautograms developed by this  
method are presented. The addition of the anionic surfactant, dioctyl  
sodium sulfosuccinate, to the emulsion was very effective for preventing  
the burst of emulsion and in obtaining a uniform spread of the emulsion  
for the wire loop method. Radioautograms obtained with this method are  
suitable for quantitative EM radioautographic studies. Details of this  
method are introduced. [Dunn and Potter DBA mouse mastocytoma cells,  
rabbit bone marrow cells, human cervical carcinoma HeLa cells and mouse  
cornea cells were used to demonstrate the utility of this method].

AB A stain for nervous tissue is described. Perfusion in sucrose formalin is  
followed by fixation in calcium acetate formalin. A preliminary  
impregnation in silver nitrate is followed by a second impregnation in  
silver proteinate buffered at pH 8.2. Reduction is by quinol activated by  
metol in a single bath containing thiosulphate. Toning is by **gold  
thiocyanate**.
